2. Concept of Computer Communication

Computer communication is defined as the exchange of data and information between two or more computing devices via a transmission medium. This process fundamentally involves four key components: a **sender** (the device initiating data transfer), a **receiver** (the device receiving data), a **communication channel** (the physical or wireless path for data), and a set of rules known as **protocols**. It facilitates the transfer of various digital information types (text, images, audio, video) through wired or wireless technologies. The primary goal is efficient information sharing and resource utilization.

3. Computer Networks A computer network is an interconnected collection of computers and devices designed to communicate and share resources, such as files, printers,

turned this whole campus into one massive, interconnected gossip network. So, understanding these principles isn't just for your grades; it's for your sanity.

2. The Whispers of Campus: Understanding Computer Communication So, what exactly is **computer communication** in our campus world? It's like you trying to tell your roommate about the absolutely ridiculous queue at the dining hall. You're the **sender**, frantically typing out your complaint. Your roommate, hopefully, is the **receiver**, reading your message. The Wi-Fi signal (or maybe that dodgy Ethernet cable you rigged up) is your **communication channel**, carrying your digital lament. And the unspoken agreement that you'll use WhatsApp for complaints and email for official stuff? Those are your **protocols** – the rules that keep campus chatter from descending into utter chaos.
